Exercise 1D

1 a $\text{RHS} = 2\sinh A \cosh A$

$$= 2\left(\frac{e^A - e^{-A}}{2}\right)\left(\frac{e^A + e^{-A}}{2}\right)$$

$$= \frac{1}{2}\left(e^{2A} - 1 + 1 - e^{-2A}\right)$$

$$= \frac{e^{2A} - e^{-2A}}{2}$$

$$= \sinh 2A = \text{LHS}$$

b $\text{RHS} = \cosh A \cosh B - \sinh A \sinh B$

$$= \left(\frac{e^A + e^{-A}}{2}\right)\left(\frac{e^B + e^{-B}}{2}\right) - \left(\frac{e^A - e^{-A}}{2}\right)\left(\frac{e^B - e^{-B}}{2}\right)$$

$$= \frac{e^{A+B} + e^{-A+B} + e^{A-B} + e^{-A-B}}{4}$$

$$\quad - \frac{e^{A+B} - e^{-A+B} - e^{A-B} + e^{-A-B}}{4}$$

$$= \frac{2\left(e^{-A+B} + e^{A-B}\right)}{4}$$

$$= \frac{e^{A-B} + e^{-(A-B)}}{2}$$

$$= \cosh(A - B) = \text{LHS}$$

c $\text{RHS} = 4\cosh^3 A - 3\cosh A$

$$= 4\left(\frac{e^A + e^{-A}}{2}\right)^3 - 3\left(\frac{e^A + e^{-A}}{2}\right)$$

$$\left(e^A + e^{-A}\right)^3 = e^{3A} + 3e^{2A}e^{-A} + 3e^A e^{-2A} + e^{-3A}$$

$$= e^{3A} + 3e^A + 3e^{-A} + e^{-3A}$$

$$\text{RHS} = \frac{e^{3A} + 3e^A + 3e^{-A} + e^{-3A}}{2} - \frac{3(e^A + e^{-A})}{2}$$

$$= \frac{e^{3A} + e^{-3A}}{2}$$

$$= \cosh 3A = \text{LHS}$$

> Use the expansion
> $(x + y)^3 = x^3 + 3x^2 y + 3xy^2 + y^3$.

1 d $RHS = 2\sin\left(\dfrac{A-B}{2}\right)\cosh\left(\dfrac{A+B}{2}\right)$

$= 2\left(\dfrac{e^{\frac{A-B}{2}} - e^{\frac{-A+B}{2}}}{2}\right)\left(\dfrac{e^{\frac{A+B}{2}} + e^{\frac{-A-B}{2}}}{2}\right)$

$= \dfrac{1}{2}\left(e^{\frac{A-B}{2}+\frac{A+B}{2}} - e^{\frac{-A+B}{2}+\frac{A+B}{2}} + e^{\frac{A-B}{2}+\frac{A-B}{2}} - e^{\frac{-A+B}{2}+\frac{-A-B}{2}}\right)$

$= \dfrac{1}{2}\left(e^{A} - e^{B} + e^{-B} - e^{-A}\right)$

$= \dfrac{1}{2}\left(e^{A} - e^{-A}\right) - \dfrac{1}{2}\left(e^{B} - e^{-B}\right)$

$= \sinh A - \sinh B$

$= LHS$

2 a $\sin(A-B) = \sin A\cos B - \cos A\sin B$

$\sinh(A-B) = \sinh A\cosh B - \cosh A\sinh B$

> Replace $\sin x$ by $\sinh x$ and $\cos x$ by $\cosh x$.

b $\sin 3A = 3\sin A - 4\sin^3 A$

$= 3\sin A - 4\sin A\sin^2 A$

$\sinh 3A = 3\sinh A + 4\sinh^3 A$

> Replace $\sin^2 A$, the product of two sine terms, by $-\sinh^2 A$.

c $\cos A + \cos B = 2\cos\left(\dfrac{A+B}{2}\right)\cos\left(\dfrac{A-B}{2}\right)$

$\cosh A + \cosh B = 2\cosh\left(\dfrac{A+B}{2}\right)\cosh\left(\dfrac{A-B}{2}\right)$

> Replace $\cos x$ by $\cosh x$.

d $\cos 2A = \dfrac{1-\tan^2 A}{1+\tan^2 A}$

$\cosh 2A = \dfrac{1+\tanh^2 A}{1-\tanh^2 A}$

> $\tan^2 A = \dfrac{\sin^2 A}{\cos^2 A}$, so there is a product of two sines.
>
> Replace $\tan^2 A$ by $-\tanh^2 A$.

e $\cos 2A = \cos^4 A - \sin^4 A$

$= \cos^4 A - (\sin^2 A)(\sin^2 A)$

$\cosh 2A = \cosh^4 A - (-\sinh^2 A)(-\sinh^2 A)$

$= \cosh^4 A - \sinh^4 A$

> Replace $\sin^2 A$ by $-\sinh^2 A$.

> Solve as a quadratic in e^x.

5 i

$$2\tanh x = \cosh x$$

$$\frac{2\sinh}{\cosh x} = \cosh x$$

$$2\sinh x = \cosh^2 x$$

Using $\cosh^2 x - \sinh^2 x = 1$

$$2\sinh x = 1 + \sinh^2 x$$

$$\sinh^2 x - 2\sinh x + 1 = 0$$

$$(\sinh x - 1)^2 = 0$$

$$\sinh x = 1$$

$$x = \text{arsinh}\,1$$

$$x = \ln(1 + \sqrt{1^2 + 1})$$

$$= \ln(1 + \sqrt{2})$$

Use $\text{arsinh}\,x = \ln\left(x + \sqrt{x^2 + 1}\right)$.

6 a

$$2\cosh^2 x - 1 = 2\left(\frac{e^x + e^{-x}}{2}\right)^2 - 1$$

$$= 2\left(\frac{e^{2x} + 2 + e^{-2x}}{4}\right) - 1$$

$$= \frac{e^{2x} + e^{-2x}}{2}$$

$$= \cosh 2x.$$

b Using the relation $\cosh 2x = 2\cosh^2 x - 1$, the equation becomes $2\cosh^2 x - 3\cosh x - 9 = 0$.
Substituting $u = \cosh x$ into this equation allows us to clearly see a quadratic equation

$2u^2 - 3u - 9 = 0$ which gives solutions $u = \dfrac{3 \pm \sqrt{9 + 72}}{4}$, we neglect the negative solution to avoid

complex numbers.
i.e.
$u = 3$.
This means that our solutions for x are the values for
$x_1 = \text{ar}\cosh(3)$.

Now recalling the expression $\text{ar}\cosh u = \ln\left(u \pm \sqrt{u^2 - 1}\right)$, we obtain the exact logarithm solutions

$x = \ln\left(3 \pm 2\sqrt{2}\right).$

7 Using the identity $\cosh^2 x - \sinh^2 x \equiv 1$, the equation in question becomes

$2\left(\cosh^2 x - 1\right) - 5\cosh x = 5$.

We simplify and use the substitution $u = \cosh x$ in order to obtain $2u^2 - 5u - 7 = 0$. This equation has

solutions $u = \dfrac{5 \pm \sqrt{25 + 56}}{4}$, we neglect the negative solution to avoid complex numbers, thus $u = \frac{7}{2}$.

This means that our solutions for x are the values for

$x = \operatorname{ar\,cosh}\left(\frac{7}{2}\right)$.

Now recalling the expression $\operatorname{ar\,cosh} u = \ln\left(u \pm \sqrt{u^2 - 1}\right)$, we obtain the exact logarithm solutions

$x = \ln\left(\frac{1}{2}\left(7 \pm 3\sqrt{5}\right)\right)$.

8 $\operatorname{sech}^2 x \equiv 1 + \tanh^2 x$ is not true, the correct identity is $\operatorname{sech}^2 x \equiv 1 - \tanh^2 x$ by Osborn's rule.
He has split the fraction via denominator on the second line. This is not valid.
In mathematics we write this as

$\dfrac{a}{b+c} \neq \dfrac{a}{b} + \dfrac{a}{c}$.

The final mistake he made was assuming that taking the reciprocal of all terms preserves the value.
This is incorrect. For example $3 + 1 \neq \frac{1}{3} + 1$.

The correct proof is

$\dfrac{1 + \tanh^2 x}{1 - \tanh^2 x} \equiv \dfrac{2 - \operatorname{sech}^2 x}{\operatorname{sech}^2 x}$

$\equiv \dfrac{2}{\operatorname{sech}^2 x} - 1$

$\equiv 2\cosh^2 x - 1$.

9 a Recall the identity $R\cosh(x + a) \equiv R\cosh x \cosh a + R\sinh x \sinh a$.
From this we can set $R\cosh a = 10$ and $R\sinh a = 6$.
In order to find values for R and a:

$\dfrac{R\sinh a}{R\cosh a} = \tanh a = \dfrac{6}{10} = \dfrac{3}{5}$

giving

$a = \operatorname{artanh}(0.6)$

$\approx 0.693 \,(3\text{ d.p.})$

We can now use the expression $R\cosh a = 10$.

To find $\cosh a$: $\operatorname{sech}^2 a = 1 - \tanh^2 a = 1 - \left(\dfrac{3}{5}\right)^2 = \dfrac{16}{25}$

$\therefore \cosh^2 a = \dfrac{1}{\operatorname{sech}^2 a} = \dfrac{25}{16}$ and so $\cosh a = \dfrac{5}{4}$

So $R = \dfrac{10}{\cosh a} = \dfrac{10}{\left(\frac{5}{4}\right)} = 8$

Thus giving us $10\cosh x + 6\sinh x = 8\cosh(x + 0.693)$.

9 b The minimum value occurs when $\cosh(x+0.693)$ is minimal. We know this occurs when $x+0.693=0$, by the graph of $\cosh x$. So the minimal value is $8\cosh 0=8$.

We could also find this answer by setting $y=8\cosh(x+0.693)$, finding the solution to

$\dfrac{dy}{dx}=8\sinh(x+0.693)=0$ as $x=-0.693$ and substituting in, to get $y=8\cosh 0=8$.

The second derivative should be checked to be positive at this point in order to conclude that the stationary point is minimal, not maximal.

c $10\cosh x+6\sinh x=8\cosh(x+0.693)=11$.

We rearrange the equation to be $\cosh(x+0.693)=\frac{11}{8}$.

Set $u=x+0.693$ and now noting the symmetry about $u=0$ we obtain two solutions,

$u=\pm\operatorname{arcosh}\left(\frac{11}{8}\right)\approx\pm0.841(3\text{ d.p.})$

This means our solutions for x are

$x_1=-1.534,$

$x_2=0.148.$
